Mixed Reality (MR) technologies, including Virtual Reality (VR) and Augmented Reality (AR), are changing the way designers, architects, engineers and manufacturers innovate, collaborate and communicate.
MIXED REALITY FOR DESIGN AND BEYOND

With new Head Mounted Displays (HMDs), powerful 3D graphics and exciting developments in professional software, Mixed Reality is set to explode in all areas of design, manufacturing and construction.

Mixed Reality (MR) for design, engineering, architecture and manufacturing has been around for decades. But it is only now that this exciting technology is starting to explode. MR has not only become more powerful, but also more affordable. It is no longer the preserve of large automotive and aerospace firms. Even small architectural practices can now get on board.

Head Mounted Displays (HMDs) like the HTC Vive and Microsoft HoloLens may be leading the charge, but there have also been huge advances in 3D graphics technology and professional software. With powerful desktop and mobile workstations and optimised workflows to move design and engineering data from CAD into mixed reality environments, MR no longer needs to be a consultancy-led technology.

THE REALITY SPECTRUM

Mixed Reality is an umbrella term that can be applied to a range of technologies along the ‘virtuality continuum’ that connects completely real environments to completely virtual ones.

At one end of the spectrum Augmented Reality (AR) broadens our perception of the real world by overlaying digital text, graphics or pictures on physical objects. This could be assembly instructions for a production line or maintenance information for a piece of machinery.

At the other end of the spectrum, Virtual Reality (VR) completely replaces the real world with a fully immersive, computer generated world. It allows the user to experience buildings prior to construction, or cars before they have been made, and to optimise the complete development process from design to manufacture.

Augmented Virtuality (AV) sits in the middle, combining the best aspects of VR and AR, allowing users to see believable 3D virtual objects alongside physical objects. This could be a car in your driveway, or a new kitchen in your home.

VR - A PHYSICAL PRESENCE

To date, the architecture, engineering and construction, and product development and manufacturing sectors have felt the biggest impact from VR. This is down to both the maturity and availability of software and hardware and the power of the technology. VR can give an incredible sense of being physically connected to a virtual product or building. It can evoke a visceral response that simply cannot be matched by viewing a 3D CAD model or photorealistic rendering or animation on a 2D screen.

But VR is not just a viewing experience. Users can interact with designs as they would in the physical world: car doors can be opened; light switches turned on; and engine parts grabbed and moved. This can be a powerful tool for design exploration, virtual prototyping, marketing or sales. VR can have a huge influence on collaborative design review, or act as an incredible communication tool for clients or customers. Engineers can be trained on virtual products before they have been built for servicing or operation.

HYPE VS REALITY

As with many new technologies, VR has experienced its fair share of hype. And it will take time before there is mainstream adoption in the design, manufacturing and construction sectors.

But the market is predicted to grow fast. Goldman Sachs anticipates ‘engineering’ will take a $4.7 billion slice by 2025 with ‘real estate’ accounting for $2.6 billion. Early adopters will benefit from being able to assess what works for them and develop and refine complex VR workflows. Those who wait for VR to go mainstream, and approach it from a standing start, could be left behind.
Fujitsu is perfectly placed to support the complete spectrum of Mixed Reality applications for product development, engineering, architecture, manufacturing and beyond.

The FUJITSU CELSIUS desktop and mobile workstations with NVIDIA® Quadro® GPUs can provide the 3D performance and reliability that professional Virtual Reality applications demand. And through close collaboration with companies like Autodesk at its VR Center of Excellence (page 3) Fujitsu can better understand the workflow requirements of designers and engineers, as well as the many challenges they face.

In the field of Augmented Reality Fujitsu is leading development, creating dynamic new workflows to support the maintenance, repair and operation of equipment. Its AR solution centres on the lightweight, rugged FUJITSU Head Mounted Display IOT001 which can be fully integrated into the company’s cloud connected UBIQUITOUSWARE range of enterprise solutions (page 12).

THE FULL SPECTRUM OF MIXED REALITY SOLUTIONS

When it comes to IT hardware, students at the London Design and Engineering University Technical College are some of the most demanding in the world. They need powerful workstations to create virtual worlds using advanced 3D software like Unreal Engine for gaming and VR, Autodesk 3ds Max and SolidWorks.

The UTC’s dedicated VR lab provides its students with 25 FUJITSU CELSIUS M740 workstations. The powerful VR Ready machines were used on a recent project to design a virtual reality Ethiopian village environment inside Unreal, to be explored with the Oculus Rift.

The UTC supports other students with 50 FUJITSU CELSIUS J550 workstations, 88 FUJITSU Desktop ESPRIMO Q556 and 40 FUJITSU Notebook LIFEBOOK U745.

VIRTUAL EDUCATION

AUTODESK VR CENTER OF EXCELLENCE

In 2017 Autodesk opened its VR Center of Excellence at its European headquarters in Munich, Germany. The VR Showroom gives customers from the automotive, design and architectural communities the opportunity to get hands-on with the very latest VR / AR and MR technologies.

The state of the art facilities, which show off the latest Autodesk professional VR software tools including Autodesk VRED, are being powered by FUJITSU CELSIUS workstations. This includes three FUJITSU CELSIUS M740 ‘VR Ready’ workstations with dual NVIDIA® Quadro® Pascal GPUs for HTC Vive.

For more information see
Mixed Reality can have a huge impact on design. Life-sized buildings can be explored before they are built. The feeling of presence and scale from a fully immersive experience is already approaching reality.

The possibilities for MR in Architecture, Engineering and Construction (AEC) are countless – from bringing clarity to design review and solving construction and serviceability issues to revolutionising client communication and producing enthralling sales and marketing experiences.

The single most compelling reason for using MR in the AEC sector is the sense of presence, proportion and scale that you get from wearing a VR headset like the HTC Vive. It can make you feel that the virtual building is truly real. The physical connection can be so strong that some users experience vertigo in potentially perilous situations.

This connection can be a hugely powerful asset. VR for design review can reveal issues that simply would not have been spotted with 2D drawings or 3D models. Architects can be encouraged to try out new ideas and get timely feedback on what does and does not work. Clients are able to understand exactly how a proposed building might function.

Taking a 3D BIM model into a VR environment has traditionally been a highly skilled process. Specialist VR agencies earn their keep through their knowledge of VR game engines (such as Unity or Unreal Engine from Epic Games), geometry and lighting optimisation. Scenes can be customised so clients can explore different design options, materials and lighting without leaving the virtual world.

But for VR to go mainstream in the AEC sector, it has to be quick and easy for non-expert users to move between BIM and VR. The good news is, this is already a reality. Autodesk Revit Live is a cloud service that is designed to take your BIM model from Revit to an interactive VR environment in two clicks. Desktop software tools Enscape and IrisVR Prospect offer a similar push button approach through Revit plug-ins. IrisVR Prospect also supports other 3D applications, including SketchUp and Rhino (through Grasshopper). Mindesk has a push button workflow from Rhino to VR.

Unreal Engine is renowned for its visual fidelity, but the pipeline for bringing in data from CAD and BIM software has historically been fragmented. Epic Games is working hard to change this with a new detailed design is currently done on the desktop in BIM and VR is used to give the architect a much better understanding of scale and space. With push-button workflows it’s possible to move between BIM and VR very quickly. In the future it may become more common to model in VR or make simple changes such as moving walls, doors, etc.

CONCEPT DESIGN

Mixed reality can deliver huge benefits throughout the entire construction process. Here we look at some of the ways various technologies are supporting new efficient workflows from concept design all the way through to operations and maintenance.

MR can be used at the very early stages of design – using massing models to explore the relationships between spaces or freeform 3D sketching and modelling tools to develop ideas. This can be done in a fully immersive environment with a VR headset or in augmented virtuality where a 3D holographic model floats on a table in the middle of a design office.

DESIGN DEVELOPMENT

Commercial buildings, office space and high-end apartments can be marketed and sold ‘off-plan’ long before they are built. VR gives the client a much better understanding and feel for a space than a traditional 2D render. The client can even change fixtures and fittings in real time. Some developers are now using VR instead of traditional show apartments.

COMMUNICATION

VR is a hugely effective communication tool. It can be used for presentations to clients, planners and for public consultations. A fully immersive VR HMD like the HTC Vive will give best results, but smartphone VR headsets like Google Cardboard can be effective. They also allow many more people to view the content.
Digital fabrication and construction models can be overlaid on top of as-built conditions during construction and refurbishment. This can provide visibility into construction progress and allow construction accuracy to be verified in real time. When errors do occur on site, they can be resolved much earlier, saving time and money.

Construction workers can be trained in VR, using life-size construction site models to help prevent accidents. By actually ‘experiencing’ potentially dangerous situations, knowledge is retained much better. When on site, AR headsets can be used to alert workers to potential hazards by overlaying pop up warnings.

Systems operation and maintenance information can be overlaid over installed equipment on site. Maintenance workflows can be communicated through stills, videos or augmented models and hands kept free. By capturing as-built conditions during construction, workers can have ‘x-ray vision’ to see utilities behind walls or underground.

VR is also having a huge impact on collaboration. Co-presence technology allows multiple users to exist in a single VR environment. Participants don’t have to be in the same physical location. A New York-based architect, for example, could collaborate on the same virtual building with a London-based engineer and a Munich-based cladding contractor.

VR interaction can go beyond a simple viewing experience. Users can access head-up display toolboxes to control layers, mark up models or explore daylighting with time and date sliders.

Software is also emerging that enables architects to design in a fully immersive environment. ArchiSpace, for example, includes a number of 3D modelling tools for use directly inside VR, as well as the ability to place and scale 3D objects.

Collaboration review sessions can be held in a CAVE, a projection-based VR display or enabled with VR or MR headsets. With ‘co-presence’ participants do not have to be in the same room, or even in the same country. Architectural, structural and MEP models can be co-ordinated and clashes identified and resolved.

4D simulation allows firms to ‘virtually’ construct and rehearse a project before ‘actual’ construction work begins. Visualisation using VR or MR can bring greater clarity to complex construction sequences and help identify and resolve potential issues before construction begins, saving time and money.

BIM models and data can be augmented over the real-world construction site to spatially orient workers and effectively convey design intent. Tasks can be displayed on voice controlled AR / MR headsets, giving easy access to data, drawings and in-context 3D models while leaving both hands free to complete manual tasks.

4D simulation

Construction

Maintenance

Site safety

Design verification

Workflow toolkit called Datasmith and tight integration with SketchUp.

For extremely high-quality and accurate visualisations, VR can be paired with a physically-based renderer. This is ideal for polished presentations and simulations but does require a lot of processing time.

Navigating around a building in VR can be done in a number of ways. For a sitting experience use a game controller or keyboard. For a room scale experience walk around the building, then teleport larger distances with a VR controller.

Users don’t have to keep their feet on the ground. During construction of NVIDIA’s new Silicon Valley HQ, for example, site managers tracked construction progress by flying around point clouds that had been scanned periodically by automated drones.

VR interaction can go beyond a simple viewing experience. Users can access head-up display toolboxes to control layers, mark up models or explore daylighting with time and date sliders.

Software is also emerging that enables architects to design in a fully immersive environment. ArchiSpace, for example, includes a number of 3D modelling tools for use directly inside VR, as well as the ability to place and scale 3D objects.
PRODUCT DEVELOPMENT AND MANUFACTURING

MR can promote a holistic development process, where design, engineering, manufacturing, operations and maintenance can all be optimised, long before committing to costly physical prototypes or production tooling.

While the automotive, aerospace and heavy machinery sectors continue to drive adoption of Mixed Reality in design and manufacturing, the combination of low cost HMDs and powerful GPUs means MR is now expanding into many different areas.

VR is driving this change and is being deployed at all stages of product development, from 3D conceptual design and virtual prototyping to factory planning and interactive mapping.

It allows products to be experienced at human scale before they are built, often in context of where they will be used. This can encourage designers to explore bold new ideas and give them the confidence to make the right decisions early on.

With a focus on render quality, VR can aid aesthetic decision making. Here, the use of physically-based materials, dynamic lighting and ambient occlusion can help make products look incredibly real. Shadows and reflections are convincing and react instantly as the user moves position. In addition, anti aliasing, which smooths the jagged edges of diagonals, can aid perceived quality assessment.

Functional and ergonomic aspects of products can also be validated. Realistic mock-ups can include motion simulation so users get a physical behavioural experience as well as a fully immersive and realistic visual experience. Parts can be ‘virtually’ assembled and disassembled for serviceability checks or training.

Manufacturing processes can be simulated to make the production line safer and more efficient.

MR can promote a holistic development process, where design, engineering, manufacturing, production, maintenance, overhaul and repair can all be optimised, long before committing to costly physical prototypes or production facilities. This can significantly reduce change orders, time to market and in-the-field operations.

Smoothing the path between CAD and MR is essential for adoption to go mainstream. Powerful professional VR tools such as moreViz, TechViz XL, ESI Group IC.IDO, Virtalis Visionary Render and WorldViz Vizard offer CAD to VR workflows for traditional high-end CAD

MIXED REALITY: FOR DESIGN AND BEYOND

Mixed Reality can deliver huge benefits throughout the entire product development process. Here we look at some of the ways the technology is supporting new efficient workflows from requirements capture, through design and manufacture, all the way to maintenance, repairs and operations.

CONCEPT DESIGN

Conceptual models, created in desktop CAD, can be viewed in VR so the designer is truly immersed inside the design. In the automotive sector, for example, this method is much cheaper and quicker than producing a physical concept vehicle. New generation tools also allow designers to 3D sketch and model inside VR at 1:1 scale.

VIRTUAL PROTOTYPING

Designers and engineers can explore human machine interaction and validate the functional aspects of a product inside VR. This includes ergonomics, reach and accessibility studies and physics-based serviceability testing. Virtual prototyping is not limited to physical objects. Engineers can also visualise simulation results using MR.

REQUIREMENTS CAPTURE

An AR headset can be used to capture the requirements for a design / engineering project using its built-in camera, microphone or 3D scanner, or Bluetooth/USB colorimeter or digital calipers. This could be to review features of current / competitive products or for capturing context (e.g. adding virtual notes and annotations to a factory layout).

DESIGN DEVELOPMENT

Designers can jump between desktop CAD and VR to properly understand the scale and proportion of products. Different iterations can be compared and contrasted. Designs can also be visualised in context, in both the virtual world and the real world - such as a car in a driveway or an electrical appliance in a kitchen.
tools such as Siemens NX and Dassault Systèmes CATIA.

Dassault Systèmes is collaborating with HTC to drive VR into the enterprise space. PTC has similar aspirations and is also heavily involved in the development of Mixed Reality applications for manufacturing with its ThingWorx Studio application which works with the Microsoft HoloLens.

Autodesk is delivering advanced VR capabilities through its product visualisation and virtual prototyping tool, Autodesk VRED, which can import many of the leading CAD file formats. The software places a big emphasis on visual quality and collaboration. Designers, engineers and other stakeholders are able to participate in interactive design review sessions, even from different geographic locations.

NVIDIA is developing Holodeck, a ‘photorealistic’ collaborative VR environment that features customisable avatars, sound and haptics.

Enterprise VR solution specialist WorldViz is also focusing on collaboration with a new tool called Visible.

Virtalis is bringing its high-end VR knowledge to the mainstream with VR4CAD, a tool designed to help firms easily connect design data sets with VR.

Custom CAD to VR workflows also exist for mainstream CAD applications. Data from Autodesk Inventor and Dassault Systèmes SOLIDWORKS, for example, can be brought into the Unity or Unreal Engine game engines via neutral file formats such as OBJ.

To help optimise CAD to VR workflows, Epic Games recently introduced Datasmith for Unreal Engine which streamlines the translation of assets including geometry, textures, materials, lights and cameras.

While VR is not currently suitable for detailed 3D modelling, software like Dassault Systèmes Dream Sketcher is demonstrating how VR can be applied to 1:1 scale conceptual 3D sketching. At the other end of the product lifecycle, Zerolight develops virtual car showrooms for leading car manufacturers such as Audi and Pagani, where customers can interact with and configure cars instantly, in incredible detail.

With MR, operators can be trained on how to use products and engineers on how to service machinery. This can cut down on shipping and travel and help ensure products are used and maintained safely and correctly. Workers can also be trained on virtual production lines, guiding them through the assembly process step by step.

Products can be marketed and sold even before they have been manufactured. Custom products can be designed and viewed in situ – e.g. a kitchen or a stair lift. Car configurators allow customers to sit inside bespoke vehicles and evaluate fabric and paint options. With VR smartphones, marketing content can reach a mass audience.

Collaborative design review can be done in a CAVE or using various HMDs. With ‘co-presence’ participants do not have to be in the same room, or even in the same country. With NVIDIA Holodeck, for example, remote collaborators are represented in VR by humanoid avatars. Design review can focus on functional testing, aesthetic evaluation and more.

Virtual production lines can be designed, and simulated using MR. Multiple what if scenarios can be assessed and the entire process optimised long before production starts, saving time and money and making the process safer. This can be done entirely in the virtual world or in the context of the physical factory where it will be installed.

For maintenance, repairs and operation, AR headsets can be set to automatically recognise equipment. Engineers can be walked through repairs using annotations or in-context 3D models, leaving both hands free for manual tasks. For additional guidance, expert engineers in a remote control centre can give assistance.
## CHECKLIST - VR FOR PRODUCT DEVELOPMENT

### WORKFLOW

**Software**

VR needs dedicated VR-capable software. VR is not possible today inside CAD software. Software should be chosen according to intended use, e.g., Autodesk VRED for aesthetic evaluation (very high-quality real-time rendering) or IC.IDO for physics-based digital mockup. Also the ease with which it is possible to move from CAD to VR.

**Data pipeline**

Some VR applications offer automated ‘push button’ workflows to import CAD data. Others require manual preparation of data. Automated workflows make things easy but lack flexibility. Manual or semi-automated workflows give the most freedom and can help you get more out of your workstation hardware, but it can be time consuming and requires specialist skills.

Geometry should be optimised to improve performance (CAD data is very heavy).

Materials can be mapped from CAD appearances or applied inside the VR application.

Lighting can be automatically taken from CAD or set up in VR. In some applications, lights can be baked into the scene to improve performance.

Consider import and re-use of non-geometric information, e.g., CAD, PLM and IoT meta data.

Build in interactivity, e.g., product animations, physics-based mechanisms and design variants.

Workflow should be ‘non-destructive’, so a lot of manual re-work is not required for every iteration.

Consider where content might be used beyond its primary application, e.g., by consumers on low-cost ‘mobile’ VR headsets or tablets.

**Consultancy**

VR can be complicated, but help is at hand. Consultancies can define custom product development workflows between CAD and VR, configure hardware or create visually rich and functional VR experiences, e.g., client presentations and car configurators.

### HARDWARE

**Workstations**

Choose between a desktop or mobile workstation. Desktop workstations can offer higher-end performance and greater expandability. Mobile workstations allow you to easily take VR anywhere – to the boardroom or a client office.

To view VR content you need a high frequency CPU (3.0GHz or higher). To create VR content, some applications can benefit from a GPU with lots of cores, e.g., for data import or light baking.

**Workstation GPU**

Many GPUs that are traditionally used for 3D CAD are not powerful enough for VR. Instead you need a GPU that is ‘VR Ready’.

The NVIDIA Quadro P6000, P5000, P6000, GP100 and GV100 are ‘VR Ready’ and also optimised and certified for 3D CAD applications, so designers get the best of both worlds when using CAD and VR. Consumer GPUs are not certified for 3D CAD.

NVIDIA Quadro ‘Pascal’ GPUs have large amounts of high-bandwidth memory, which is important for handling large engineering datasets quickly. Consumer GPUs do not have as much.

GPUs should be matched to VR workflows. More powerful GPUs are required for larger datasets, enhanced realism (physically-based materials, dynamic lighting and ambient occlusion), and smoother lines with Anti-Aliasing, which is important for styling.

Some VR applications can harness the power of two GPUs (each GPU renders its own eye).

**Head Mounted Displays (HMDs)**

For a fully immersive VR experience there are currently three main options (HTC Vive, Oculus Rift and Windows Mixed Reality Headsets). In general, the HTC Vive offers a more polished, room scale experience, while the Oculus Rift and Windows Mixed Reality Headset are known for their ease of setup and portability. The HTC Vive can also offer a cable-free experience with the TPCast wireless adapter and forthcoming Vive Wireless Adaptor.

**Environment / Setup**

**Choose your experience**

Choose between a seated experience or a roaming ‘room scale’ experience.

A seated experience is good for jumping quickly between CAD and VR for design validation or when creating a VR experience.

A ‘room scale’ experience is good for design review or for customer presentations. Explore a car from any angle or walk around a factory assembly line and teleport larger distances.

**Seated experience**

For setup, place Oculus Rift sensors on a desk and HTC Vive lighthouse emitters on camera tripods or wall mount brackets behind the desk. Interact with keyboard, mouse or VR controllers.

Multiple Vive lighthouse emitters in one office can cause interference, so there are some challenges to overcome for mass adoption. Interference can also be caused by mirrors or direct sunlight.

**Room scale experience**

Works best in a dedicated room with up to 5m x 5m of floor space (min 1.5m x 2m). No trip hazards.

HTC Vive lighthouse emitters should be mounted at opposite corners of the room, on the wall or on telescopic camera tripods. The Oculus Rift sometimes requires a third sensor.

Interact using VR controllers and additional devices (such as HTC’s tracker).

Consider HMD cables. Trailing floor cables can be a trip hazard and contravene health and safety policies. Use metal frames or ceiling mounts to route cables above head height. The HTC Vive Business Edition includes a 5m extension. Eliminate cables altogether with next generation wireless HMDs.

Consider power for all devices and data cables. USB extension cables for movement sensors.
HTC VIVE BUSINESS EDITION + VIVE PRO

The HTC Vive Business Edition is a Head Mounted Display (HMD) that provides a fully immersive VR experience. The wearer gets a real sense of presence – of being inside the virtual world – and typically feels completely cut off from the physical world.

Each eye has its own display optic, which shows a slightly offset view of the same computer generated 3D model. This ‘stereoscopic’ effect fools the brain into thinking it is seeing ‘life-sized’ objects. There is an incredible sense of scale and depth.

Virtual objects can be viewed from any angle, simply by moving your head. All movements are tracked by the Vive and bespoke trackers. As soon as you change position, the view of the virtual world updates ‘instantly’.

Users interact with the virtual world using a pair of VR controllers (one for each hand). These can then be used to move, point at, mark up or create virtual objects, or to teleport around the virtual world.

The Vive needs a workstation with a powerful professional Graphics Processing Unit (GPU). It is tethered to the machine via a long cable. Wireless adapters are starting to emerge, including one from TPCast. HTC is also set to launch its own Vive Wireless Adaptor later this year.

HTC has also released a new enterprise focused HMD. The HTC Vive Pro features dual-OLED displays at 2,880 x 1,600 resolution (1,440 x 1,600 per eye) – a 78 per cent increase from the 2,160 x 1,200 (1,080 x 1,200 per eye) resolution of the HTC Vive Business Edition.

MICROSOFT HOLOLENS

The Microsoft HoloLens is a Mixed Reality headset which has an integrated holographic computer. The glasses are semi-transparent so the wearer sees both virtual objects (holograms) and real objects alongside each other in the physical world.

The HoloLens optical system works in conjunction with multiple advanced sensors that are built into the headset and continually track its position.

Instead of using external tracking sensors, the so-called “inside-out” tracking technology recognises surfaces and features within a room and orients itself automatically. Holograms are locked relative to those features so remain in the same position, regardless of which angle they are viewed from. With everything built into the headset, it does not need to be tethered to a workstation.

Unlike the HTC Vive, Oculus Rift and Windows Mixed Reality headsets, which rely on hand controllers, the primary way to interact with the HoloLens is through hand gestures. This includes the air tap, where you hold your hand out in front of you, tap your finger down, then quickly up again. The HoloLens also responds to voice commands.

One limitation of the HoloLens is that it has a relatively limited field of view. This means the wearer can only see holograms in their line of sight and not in their peripheral vision.

To make the HoloLens suitable for use in environments with strict safety requirements, such as a construction site, AEC technology provider Trimble has developed a hard hat that fits ‘safely and securely’ on to the HoloLens.

FUJITSU UBQUITOUSWARE HEAD MOUNTED DISPLAY (HMD) IOT001

The lightweight Fujitsu Head Mounted Display (HMD) can be used for a variety of workplace AR applications, including construction, operations and maintenance. It features a heads-up, non-see-through display that can be worn on either side of the head. For optimum visibility, brightness is adjusted automatically by a built in light sensor.

As the display is positioned only over one eye and slightly below the natural line of sight, the operator can work with a clear view and maintain excellent visibility of his or her surroundings at all times. This, together with the fact that the HMD can be worn with a standard hard hat, makes it particularly attractive for use in environments with strict safety requirements, such as a construction site, plant or factory. The device is also water and shock resistant.

The heads-up display can be used to view documents, video and AR overlays. It cannot display 3D holographic models like the Microsoft HoloLens.

The HMD has a built in camera that can be used to capture photographs or videos with simple voice commands.

The Android device features Bluetooth and can be paired with a smartphone or tablet as well as a wearable Fujitsu keyboard. The tablet can then link to a range of cloud services over 3G/LTE or WiFi, including IP calls for voice or video.

To extend the range of engineering data that can be captured in the field, the Fujitsu HMD can also connect to other devices, such as a microscope, infrared scanner or digital callipers.
Virtual Reality is extremely computationally intensive, as every frame must be rendered in real time. As a result, it is essential to match your HMD with professional VR-optimised workstation hardware. Latency throughout the entire VR system must be low in order for the HMD’s display to respond almost instantly to head movements. The workstation must also deliver a consistent 90 frames per second (FPS) or more, which is almost four times as much as the accepted minimum 24 FPS for 3D CAD work on a 2D display.

If latency is more than 20 milliseconds or the workstation cannot maintain 90 FPS, the VR experience can be compromised. Users can become disoriented, as what they are seeing on the HMD is not completely in sync with their head movement in the real world. Worst of all, this can lead to feelings of nausea or motion sickness.

The responsibility of delivering extremely high refresh rates lies with the Graphics Processing Unit (GPU). VR needs an extremely powerful GPU — much more powerful than one typically used for 3D CAD.

VR not only pushes the computational limits of GPU hardware, but can place huge demands on GPU memory size and memory bandwidth. Complex 3D geometry and textures need to load into GPU memory quickly and then stay there so they can be accessed quickly. To help professionals choose workstation hardware for the best VR experience, GPU manufacturer NVIDIA has developed the NVIDIA VR Ready program. Any workstation that bears the ‘NVIDIA VR Ready’ badge is deemed to satisfy or surpass the minimum recommended hardware specifications.

This includes one or two NVIDIA Quadro P4000, P5000, P6000, GP100 or GV100 GPUs, an Intel Core i5-490 / Intel Xeon E3-1240 v3 or greater CPU, 8GB+ RAM and an HTC Vive or Oculus Rift HMD. If the workstation is to be used for VR content creation (in addition to VR consumption) as well as for other design viz workflows, then you may need to consider a workstation with even more power.

Multiple GPUs can be used to accelerate physically-based renderers such as NVIDIA Iray (found in SOLIDWORKS Visualize and Siemens NX Ray Traced Studio) or Chaos Group V-Ray RT for Autodesk Revit, 3ds Max and others. Physically accurate VR, which brings the accuracy of physically-based rendering to interactive VR, also relies on multiple GPUs to render the multiple panoramic images for each viewpoint.

CPUs with more cores can also be used to reduce render times in physically-based renderers like Luxion KeyShot and Autodesk VRED or to accelerate CAD to VR workflows, including data import / geometry optimisation and light baking.

NVIDIA QUADRO GPUs FOR OPTIMISED VR

NVIDIA's ultra high-end Quadro GPUs are designed specifically for demanding VR workflows. The Quadro P4000 (8GB), P5000 (16GB), P6000 (24GB), GP100 (16GB) and GV100 (32GB) all have NVIDIA's ‘VR Ready’ seal of approval. According to NVIDIA, the NVIDIA Quadro P6000 delivers up to 80% more performance than the previous generation Quadro M6000, based on an internal NVIDIA VR benchmark.

The dual height, 250W GPU features 24GB of GDDR5 memory, which is an important consideration for professional VR. Complex engineering geometry and detailed textures can take up a lot of GPU memory. Indeed, NVIDIA has shown how some VR workflows are already pushing the limits of GPU memory by filling all 24GB with a fully detailed Nissan automotive model. Memory can be a big differentiator over consumer GPUs, which are focused on gaming.

For the most demanding VR workflows, it is also possible to use multiple GPUs together, either by assigning each GPU to a specific eye or rendering different parts of the display. The technology that supports this mode of operation is called Scalable Link Interface (SLI). ESI Group, for example, recommends a workstation with two ultra high end NVIDIA Quadro GPUs when running its IC.IDO software on an HTC Vive. Autodesk also supports NVIDIA VR SLI for Autodesk VRED and has found that the performance improvement of two NVIDIA GPUs over one can range from 40% to 100%.
**VR READY FUJITSU WORKSTATIONS**

With professional grade NVIDIA Quadro GPUs and Intel Xeon CPUs, FUJITSU CELSIUS workstations are optimised to deliver a realistic and comfortable VR experience. Engineered and built in Germany, FUJITSU CELSIUS workstations have gained a reputation for being reliable and whisper quiet, thanks to advanced thermal management. A screwless access system also makes them highly serviceable, which helps minimise downtime when upgrading components. Comprehensive ISV certifications help ensure professional 3D CAD and BIM applications run smoothly.

Fujitsu offers three desktop workstations that are NVIDIA ‘VR Ready’: the single processor, FUJITSU CELSIUS W580power+, the single processor FUJITSU CELSIUS M770, plus the dual processor FUJITSU CELSIUS R970. Designers, engineers and architects can also take VR wherever they want with the 15.6-inch H780 or the 17-inch H980 mobile workstations, both of which are optimised for CAD and VR.

• Produced in Germany |
| **FUJITSU CELSIUS H980** | Intel® Xeon® E-2186M (6 Cores, 2.9 up to 4.6 GHz) | NVIDIA® Quadro® P5200 (mid-range VR workflows) | 32 GB or 64 GB DDR4, 2,400 MHz | 512 GB or 1TB PCIe-SSD, NVMe, M.2 module, SED | • Fundamental biometric authentication through vein pattern recognition  
• Full monitor connectivity: 2x DisplayPort via USB Type-C™, 1x full-size DisplayPort and 1x VGA  
• Thunderbolt 3 port replicator  
• Produced in Germany |
| **FUJITSU CELSIUS W580power+** | Intel® Xeon® E-2186G (6 cores, 3.8 up to 4.7 GHz) | NVIDIA® Quadro® P4000 | 32 GB or 64 GB DDR4 ECC 2,666 MHz | 256 GB or 512 GB PCIe-SSD, M.2 NVMe, + 4 TB HDD SATA III, 7,200 rpm, 3.5-inch, business critical | • Industry-first 21 litre desktop workstation & cable-free design  
• Cold-plug Technology: Storage accessible via a front disk tray  
• Smallest full-featured VR-ready desktop workstation among Tier 1 vendors  
• Produced in Germany |
| **FUJITSU CELSIUS M770 / CELSIUS M770x** | For CAD-centric VR: Intel® Xeon® W-2125 (4 cores, 4.0 up to 4.5 GHz)  
For Media-centric VR: Intel® Core™ i9 7900X (10 cores, 3.3 up to 4.3 GHz) | 1 or 2 NVIDIA® Quadro® P5000 (mid-range VR workflows) | 32 GB or 64 GB DDR4 ECC 2,666 MHz (maximum 256 GB) | 512 GB or 1 TB PCIe-SSD, M.2 NVMe, + 4 TB HDD SATA III, 7,200 rpm, 3.5-inch, business critical | • Easy serviceability: Cable-free design with green touchpoints  
• Cold-plug Technology: Storage accessible via a front disk tray  
• Smart Power Supply: iPMI-IPM displays Field Replaceable Unit (FRU) information  
• Produced in Germany |
| **FUJITSU CELSIUS R970** | For CAD / Media VR: 2 x Intel® Xeon® Gold 6144 (8 cores, 3.5 up to 4.1 GHz)  
For high-end Media / VR: 2 x Intel® Xeon® Gold 6136 (12 cores, 3.0 up to 3.3 GHz) | NVIDIA® Quadro® P5000 (mid-range VR workflows) | 64 GB or 128 GB DDR4 ECC 2,666 MHz (maximum 1 TB) | 512 GB or 1 TB PCIe-SSD, M.2 NVMe, + 4 TB HDD SATA III, 7,200 rpm, 3.5-inch, business critical | • Selection of top-quality components for 24/7 usage  
• Whisper quiet: 23 dB(A)  
• Designed, engineered and produced in Germany |
The process of maintaining, repairing and operating equipment in the field or machinery in large scale facilities like buildings, plants, factories and warehouses is ripe for optimisation. And AR is the perfect technology to help do just that. The FUJITSU UBIQUITOUSWARE Head Mounted Display IOT001 and its cloud technology backbone can help improve first time fix rates, guide less experienced workers through complex procedures or reduce the need for ‘return to base’ repairs. Workers can use the HMD to service and inspect equipment safely — making repairs, changing parts or recording results ‘hands-free’ using voice commands. This is particularly important when working at heights or in precarious environments, such as plants or construction sites, where both hands are needed at all times.

Through the heads-up display, engineers can view up-to-date information from the cloud, such as maintenance records or installation procedures. AR overlays can enhance the view of a piece of equipment and help workers understand complex operations quickly and easily. A simple annotation could be used to highlight a specific terminal on an electrical distribution board or an animated arrow could show which direction a valve should be turned.

With AR Process Flow, engineers can be guided step-by-step through a supported repair process to help ensure tasks are completed quickly and accurately. This can help avoid operational procedures being performed in the wrong order or missed out entirely, which can result in damage to equipment or risks to health and safety.

Of course, it might not be practical to document all maintenance tasks and not every engineer can be familiar with all types of equipment. On-site repairs can also throw up unforeseen challenges that cannot be solved by less experienced workers. To help support these workers on-site, experts in a control centre can be called upon for advice. Using the HMD’s front facing camera and an IP video call, the supporting engineer can see everything the on-site worker can see and then advise accordingly. Videos and photos with overlaid comments can also be relayed to communicate precise instructions. Once a repair is completed it can be documented and logged in the cloud system while the worker is still on site.

The Fujitsu solution can also help firms deploy engineering knowledge more efficiently. A single experienced engineer can support multiple workers on site, helping reduce costs and bridge the growing engineering skills gap (see box below). Couriers could also be trained to perform simple assembly or installation tasks at customer sites and document completion with photographs. This can save firms money as such tasks may have traditionally been carried out by an experienced engineer.

The engineering skills gap is a growing concern for many world economies. Engineering UK’s 2018 report highlights that 61% of businesses lack confidence there will be enough people with the skills to fill their high-skilled job vacancies. And the gap looks set to grow bigger in the coming years.

AR can help tackle this issue through more efficient deployment of engineering expertise and better capture of engineering knowledge. Fujitsu’s AR technology provides easy-to-use tools to help engineers with basic IT skills to create step-by-step workflows for repair processes that can be deployed throughout an organisation. The entire workflow can be created on site using the AR headset for image / video capture and a Bluetooth-linked Android tablet to define the details. The interactive content can then be used to train future engineers on the job. AR can also help retain engineering expertise for longer by extending the careers of an ageing workforce. Engineers who may not have been able to keep up with the physical demands of on-site maintenance and repairs, can share their knowledge through remote support from the comfort of the control centre (see above).
