White Paper
FUJITSU Server PRIMEQUEST
Performance Report PRIMEQUEST 3800B/3800E/3400E

This document contains a summary of the benchmarks executed for the FUJITSU Server PRIMEQUEST PRIMEQUEST 3800E/3800B/3400E.
The PRIMEQUEST 3800E/3800B/3400E performance data are compared with the data of other PRIMERGY models and discussed. In addition to the benchmark results, an explanation has been included for each benchmark and for the benchmark environment.

Technical data

Decimal prefixes according to the SI standard are used for measurement units in this white paper (e.g. 1 GB = 10^9 bytes). In contrast, these prefixes should be interpreted as binary prefixes (e.g. 1 GB = 2^30 bytes) for the capacities of caches and memory modules. Separate reference will be made to any further exceptions where applicable.

**Per system board:**

- Chipset: Intel® C621 Chipset
- Number of sockets: 2
- Number of processors orderable: 2
- Processor type: Intel® Xeon® Processor Scalable Family
- Number of memory slots: 24 (12 per processor)
- Maximum memory configuration: 3TB

**Per I/O unit:**

- Onboard LAN controller: none
- PCI slots:
  - PRIMEQUEST 3800B: 4 x PCI-Express 3.0 x 8, 4 x PCI-Express 3.0 x16
  - PRIMEQUEST 3800E: 1 x PCI-Express 3.0 x 8, 1 x PCI-Express 3.0 x16
  - PRIMEQUEST 3400E: 2 x 10 Gbit/s Ethernet (RJ45)

**Per disk unit:**

- Max. number of internal hard disks: 8, 24

All the processors that can be ordered with the PRIMEQUEST 3800E/3800B/3400E support Intel® Turbo Boost Technology 2.0. This technology allows you to operate the processor with higher frequencies than the nominal frequency. Listed in the processor table is "Max. Turbo Frequency" for the theoretical frequency maximum with only one active core per processor. The maximum frequency that can actually be achieved depends on the number of active cores, the current consumption, electrical power consumption and the temperature of the processor.

As a matter of principle Intel does not guarantee that the maximum turbo frequency will be reached. This is related to manufacturing tolerances, which result in a variance regarding the performance of various examples of a processor model. The range of the variance covers the entire scope between the nominal frequency and the maximum turbo frequency.

The turbo functionality can be set via BIOS option. Fujitsu generally recommends leaving the "Turbo Mode" option set at the standard setting "Enabled", as performance is substantially increased by the higher frequencies. However, since the higher frequencies depend on general conditions and are not always guaranteed, it can be advantageous to disable the "Turbo Mode" option for application scenarios with intensive use of AVX instructions and a high number of instructions per clock unit, as well as for those that require constant performance or lower electrical power consumption.

SPECcpu2006

Benchmark description

SPECcpu2006 is a benchmark which measures the system efficiency with integer and floating-point operations. It consists of an integer test suite (SPECint2006) containing 12 applications and a floating-point test suite (SPECfp2006) containing 17 applications. Both test suites are extremely computing-intensive and concentrate on the CPU and the memory. Other components, such as Disk I/O and network, are not measured by this benchmark.

SPECcpu2006 is not tied to a special operating system. The benchmark is available as source code and is compiled before the actual measurement. The used compiler version and their optimization settings also affect the measurement result.

SPECcpu2006 contains two different performance measurement methods: the first method (SPECint2006 or SPECfp2006) determines the time which is required to process single task. The second method (SPECint_rate2006 or SPECfp_rate2006) determines the throughput, i.e. the number of tasks that can be handled in parallel. Both methods are also divided into two measurement runs, “base” and “peak” which differ in the use of compiler optimization. When publishing the results the base values are always used; the peak values are optional.

</table>

The measurement results are the geometric average from normalized ratio values which have been determined for individual benchmarks. The geometric average - in contrast to the arithmetic average - means that there is a weighting in favour of the lower individual results. Normalized means that the measurement is how fast is the test system compared to a reference system. Value “1” was defined for the SPECint_base2006, SPECint_rate_base2006, SPECfp_base2006 and SPECfp_rate_base2006 results of the reference system. For example, a SPECint_base2006 value of 2 means that the measuring system has handled this benchmark twice as fast as the reference system. A SPECfp_rate_base2006 value of 4 means that the measuring system has handled this benchmark some 4/# base copies times faster than the reference system. “# base copies” specify how many parallel instances of the benchmark have been executed.

Not every SPECcpu2006 measurement is submitted by us for publication at SPEC. This is why the SPEC web pages do not have every result. As we archive the log files for all measurements, we can prove the correct implementation of the measurements at any time.

Benchmark results

In terms of processors the benchmark result depends primarily on the size of the processor cache, the support for Hyper-Threading, the number of processor cores and on the processor frequency. In the case of processors with Turbo mode the number of cores, which are loaded by the benchmark, determines the maximum processor frequency that can be achieved. In the case of single-threaded benchmarks, which largely load one core only, the maximum processor frequency that can be achieved is higher than with multi-threaded benchmarks.

This result with "est." is an estimated value.

PRIMEQUEST 3800E/3800B/3400E vs. PRIMEQUEST 2800E3/2800B3
SPECCpu2017

Benchmark description

SPECCpu2017 is a benchmark which measures the system efficiency with integer and floating-point operations. It consists of an integer test suite (SPECrate 2017 Integer, SPECSpeed 2017 Integer) containing 10 applications and a floating-point test suite (SPECrate 2017 Floating Point, SPECSpeed 2017 Floating Point) containing 14 applications. Both test suites are extremely computing-intensive and concentrate on the CPU and the memory. Other components, such as Disk I/O and network, are not measured by this benchmark.

SPECCpu2017 is not tied to a special operating system. The benchmark is available as source code and is compiled before the actual measurement. The used compiler version and their optimization settings also affect the measurement result.

SPECCpu2017 contains two different performance measurement methods: The first method (SPECSpeed 2017 Integer or SPECSpeed 2017 Floating Point) determines the time which is required to process a single task. The second method (SPECrate 2017 Integer or SPECrate 2017 Floating Point) determines the throughput, i.e. the number of tasks that can be handled in parallel. Both methods are also divided into two measurement runs, “base” and “peak”, which differ in the use of compiler optimization. When publishing the results, the base values are always used and the peak values are optional.

The measurement results are the geometric average from normalized ratio values which have been determined for individual benchmarks. The geometric average - in contrast to the arithmetic average - means that there is a weighting in favor of the lower individual results. Normalized means that the measurement is how fast is the test system compared to a reference system. Value “1” was defined for the SPECSpeed2017_int_base, SPECrate2017_int_base, SPECSpeed2017_fp_base, and SPECrate2017_fp_base results of the reference system. For example, a SPECSpeed2017_int_base value of 2 means that the measuring system has handled this benchmark twice as fast as the reference system. A SPECrate2017_fp_base value of 4 means that the measuring system has handled this benchmark some 4[# base copies] times faster than the reference system. “# base copies” specifies how many parallel instances of the benchmark have been executed.

Not every SPECCpu2017 measurement is submitted by us for publication at SPEC. This is why the SPEC web pages do not have every result. As we archive the log files for all measurements, we can prove the correct implementation of the measurements at any time.

Benchmark results

In terms of processors the benchmark result depends primarily on the size of the processor cache, the support for Hyper-Threading, the number of processor cores and on the processor frequency. In the case of processors with Turbo mode the number of cores, which are loaded by the benchmark, determines the maximum processor frequency that can be achieved. In the case of single-threaded benchmarks, which largely load one core only, the maximum processor frequency that can be achieved is higher than with multi-threaded benchmarks.

This result with "est." is an estimated value.

On 4th Sep. 2018 the PRIMEQUEST 3800B with eight Xeon Platinum 8180 processors was ranked first in the 8-socket systems category for the benchmark SPECrate2017_fp_base.

The current results can be found at [http://www.spec.org/cpu2017/results](http://www.spec.org/cpu2017/results).
**SAP SD**

**Benchmark description**

The SAP application software consists of modules used to manage all standard business processes. These include modules for ERP (Enterprise Resource Planning), such as Assemble-to-Order (ATO), Financial Accounting (FI), Human Resources (HR), Materials Management (MM), Production Planning (PP) plus Sales and Distribution (SD), as well as modules for SCM (Supply Chain Management), Retail, Banking, Utilities, BI (Business Intelligence), CRM (Customer Relation Management) or PLM (Product Lifecycle Management).

The application software is always based on a database so that a SAP configuration consists of the hardware, the software components operating system, zhe database and the SAP software itself.

SAP AG has developed SAP Standard Application Benchmarks in order to verify the performance, stability and scaling of a SAP application system. The benchmarks, of which SD Benchmark is the most commonly used and most important, analyze the performance of the entire system and thus measure the quality of the integrated individual components.

The benchmark differentiates between a 2-tier and a 3-tier configuration. The 2-tier configuration has the SAP application and database installed on one server. With a 3-tier configuration the individual components of the SAP application can be distributed via several servers and an additional server handles the database.

The entire specification of the benchmark developed by SAP AG, Walldorf, Germany can be found at: [http://www.sap.com/benchmark](http://www.sap.com/benchmark).

The SAP BW Edition for SAP HANA Standard Application Benchmark

With the increasing importance of SAP HANA and in particular SAP Business Warehouse (SAP BW) on HANA, a new benchmark was introduced in July 2016: the SAP BW Edition for SAP HANA Standard Application Benchmark, referred to as SAP BWH Benchmark in the following.

The benchmark represents a typical mid-size customer scenario and volumes and utilizes the new capabilities of SAP HANA which enable customers to enhance their BW processes.

Since its first edition in 2016, the SAP BWH Benchmark has been further developed and adapted to customer requirements. In the meantime SAP BWH Benchmark version 3 is available.

Comparability of SAP BW Benchmark Results

The SAP BWH Benchmark goes beyond the scope and features used in the BW-AML benchmark. While BW-AML focuses on traditional BW objects and processes supported by all database platforms, the SAP BWH Benchmark takes advantage of HANA’s new features. The workload of the two benchmarks completely differ and thus are not comparable.

Within the SAP BW Benchmark, both the data model and the query definitions have changed in the course of the development of version 1 to version 3. That is why the results of different versions must not be compared with each other.

BWH Benchmark version 3 for instance is available for SAP HANA 2.0 only and the Data Load KPI (Phase 1) has been changed - the runtime of the latest data set (1.3 billion records) will be the KPI.

In SAP BW Benchmark version 2 it was allowed to activate a specific SAP HANA performance enhancement function which materializes intermediate query results. Benchmarks that have used the feature cannot be compared with benchmarks that haven’t. Whether the function was used can be seen in the details on www.sap.com/benchmark, “Materializing of the intermediate result of the query was enabled (phase 2 and phase 3)” is shown.

In addition, SAP BW Benchmark results with different number of data sets cannot be compared either. Currently released version of the benchmark is version 3. Benchmarks with the older versions won’t be certified anymore.

Features of the SAP BW Edition for SAP HANA Standard Application Benchmark

The SAP BWH Benchmark consists of 3 phases:

- Data load phase
- Query throughput phase
- Query runtime phase

Data load phase

The data flow starts with a data load from the source object into the corporate memory layer. The source object is shipped with the backup.

The source object contains 1.3 billion records (= 1 data set). It is possible to load this data set of 1.3 billion records multiple times.

The data set stored in the source is fetched and propagated through the different layers in 25 load cycles. In other words, 1 load cycle processes 1/25 of the data set.

One of the central rules of the benchmark stipulates that the memory utilization must be at least 65 percent. The permissible data volumes are a multiple of 1.3 billion initial data records.

The data load phase takes several hours and is a combination of CPU- and IO-intensive load. When several HANA nodes are used (see “SAP HANA Scale-up and Scale-out Configuration Architecture” below), significant network load is generated.
Query throughput phase

The queries for the throughput phase must be executed via an ABAP program with a variant containing 190 query steps. Users execute the set of navigation steps in random order (via asynchronous RFCs). The queries contain typical query patterns which can be found in BW productive systems of customers.

The query throughput phase runs one hour and is CPU bound. In a HANA multi-node environment, also significant network load is generated.

Query runtime phase

For the query runtime phase the same ABAP program as for the throughput phase is used with a different variant. The variant contains 10 queries which are executed sequentially. These queries are used to measure the runtime. They contain complex query patterns which are executed in BW productive systems of customers but which are typically not executed by many users in parallel but selectively by some power users. Therefore they are executed sequentially.

The query runtime phase takes a short time and generates a small load. Only a few processors cores are used, single thread performance is important for short runtimes.

Metrics of the SAP BW Edition for SAP HANA Standard Application Benchmark

The SAP BW edition for SAP HANA Benchmark Version 3 KPIs are:

- Benchmark phase 1 - data load phase:
  Number of initial records
  Runtime of last data set in seconds

- Benchmark phase 2 - query throughput phase:
  Query executions per hour
  CPU utilization of database server in percent

- Benchmark phase 3 - query runtime phase:
  Total runtime of complex query phase in seconds
**SAP HANA Scale-up and Scale-out Configuration Architecture**

In general, a single database node or multiple database nodes can be used for SAP benchmarks to scale the workload. In the context of SAP HANA and particularly the SAP BW Edition for SAP HANA Standard Application Benchmark it is referred to as a scale-up configuration in the case of a single database node and a scale-out configuration in the case of multi database nodes.

Although an application server is involved in the benchmark, neither performance metrics are measured nor does the server appear on the benchmark certificate.

Certified and published SAP BWH Benchmarks are published on SAP’s benchmark site [here](http://ts.fujitsu.com/primequest).
Certification date: 2018-11-06
Certification number: 2018047

**Concluding remarks**

Available now for over 20 years the CPU and memory demanding SAP SD benchmark has served well to demonstrate the strength or weakness of a hardware platform. SAP certified results will be published on SAP’s web site and comprise information on machines, platform partner, SAP® Business Suite component and the number of benchmark users. Each of the tables contains basic information about the certified results. In line with SAP’s full disclosure policy more detailed information about each result can be obtained from the respective hardware partner or SAP.
OLTP-2

Benchmark description

OLTP stands for Online Transaction Processing. The OLTP-2 benchmark is based on the typical application scenario of a database solution. In OLTP-2 database access is simulated and the number of transactions achieved per second (tps) determined as the unit of measurement for the system.

In contrast to benchmarks such as SPECint and TPC-E, which were standardized by independent bodies and for which adherence to the respective rules and regulations are monitored, OLTP-2 is an internal benchmark of Fujitsu. OLTP-2 is based on the well-known database benchmark TPC-E. OLTP-2 was designed in such a way that a wide range of configurations can be measured to present the scaling of a system with regard to the CPU and memory configuration.

Even if the two benchmarks OLTP-2 and TPC-E simulate similar application scenarios using the same load profiles, the results cannot be compared or even treated as equal, as the two benchmarks use different methods to simulate user load. OLTP-2 values are typically similar to TPC-E values. A direct comparison, or even referring to the OLTP-2 result as TPC-E, is not permitted, especially because there is no price-performance calculation.

Further information can be found in the document Benchmark Overview OLTP-2.

Benchmark environment

The measurement set-up is symbolically illustrated below:

All results were determined by way of example on a PRIMEQUEST 3800E.

**Benchmark results**

Database performance greatly depends on the configuration options with CPU, memory and on the connectivity of an adequate disk subsystem for the database. In the following scaling considerations for the processors we assume that both the memory and the disk subsystem has been adequately chosen and is not a bottleneck.

A guideline in the database environment for selecting main memory is that sufficient quantity is more important than the speed of the memory accesses. This why a configuration with a total memory of 1536 GB was considered for the measurements with two processors, a configuration with a total memory of 3072 GB for the measurements with four processors and a configuration with a total memory of 6144 GB for the measurements with eight processors. The memory configurations had memory access of 2666 MHz.

BCPUs 6144GB
4CPUs 3072GB
2CPUs 1536GB
The following diagram shows the OLTP-2 transaction rates that can be achieved with one and two processors of the Intel® Xeon® Processor Scalable Family.

The features of the processors are summarized in the section “Technical data”. The relatively large performance differences between the processors can be explained by their features. The values scale on the basis of the number of cores, the size of the L3 cache and the CPU clock frequency and as a result of the features of Hyper-Threading and turbo mode, which are available in most processor types. Furthermore, the data transfer rate between processors (“UPI Speed”) also determines performance.

Within a group of processors with the same number of cores scaling can be seen via the CPU clock frequency.

If you compare the maximum achievable OLTP-2 values of the current system generation with the values that were achieved on the predecessor systems, the result is an increase of about 83%.

![Diagram showing OLTP-2 transaction rates comparison](image)
vServCon

Benchmark description

vServCon is a benchmark used by Fujitsu to compare server configurations with hypervisor with regard to their suitability for server consolidation. This allows both the comparison of systems, processors and I/O technologies as well as the comparison of hypervisors, virtualization forms and additional drivers for virtual machines.

vServCon is not a new benchmark in the true sense of the word. It is more a framework that combines already established benchmarks (or in modified form) as workloads in order to reproduce the load of a consolidated and virtualized server environment. Three proven benchmarks are used which cover the application scenarios database, application server and web server.

<table>
<thead>
<tr>
<th>Application scenario</th>
<th>Benchmark</th>
<th>No. of logical CPU cores</th>
<th>Memory</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Sysbench (adapted)</td>
<td>2</td>
<td>1.5 GB</td>
</tr>
<tr>
<td>Java application server</td>
<td>SPECjbb (adapted, with 50% - 60% load)</td>
<td>2</td>
<td>2 GB</td>
</tr>
<tr>
<td>Web server</td>
<td>WebBench</td>
<td>1</td>
<td>1.5 GB</td>
</tr>
</tbody>
</table>

Each of the three application scenarios is allocated to a dedicated virtual machine (VM). Add to these a fourth machine, the so-called idle VM. These four VMs make up a “tile”. Depending on the performance capability of the underlying server hardware, you may as part of a measurement also have to start several identical tiles in parallel in order to achieve a maximum performance score.

Each of the three vServCon application scenarios provides a specific benchmark result in the form of application-specific transaction rates for the respective VM. In order to derive a normalized score, the individual benchmark results for one tile are put in relation to the respective results of a reference system. The resulting relative performance values are then suitably weighted and finally added up for all VMs and tiles. The outcome is a score for this tile number.

Starting as a rule with one tile, this procedure is performed for an increasing number of tiles until no further significant increase in this vServCon score occurs. The final vServCon score is then the maximum of the vServCon scores for all tile numbers. This score thus reflects the maximum total throughput that can be achieved by running the mix defined in vServCon that consists of numerous VMs up to the possible full utilization of CPU resources. This is why the measurement environment for vServCon measurements is designed in such a way that only the CPU is the limiting factor and that no limitations occur as a result of other resources.

The progression of the vServCon scores for the tile numbers provides useful information about the scaling behavior of the “System under Test”.

A detailed description of vServCon is in the document: Benchmark Overview vServCon.

---

*Note: The chart shows the performance scores for various processor configurations. The scores range from 0 to 250, with higher scores indicating better performance.*
The relatively large performance differences between the processors can be explained by their features. The values scale on the basis of the number of cores, the size of the L3 cache and the CPU clock frequency and as a result of the features of Hyper-Threading and turbo mode, which are available in most processor types. Furthermore, the data transfer rate between processors ("UPI Speed") also determines performance. Within a group of processors with the same number of cores scaling can be seen via the CPU clock frequency. As a matter of principle, the memory access speed also influences performance. A guideline in the virtualization environment for selecting main memory is that sufficient quantity is more important than the speed of the memory accesses. The vServCon scaling measurements presented here were all performed with a memory access speed of 2666 MHz.
Until now we have looked at the virtualization performance of a fully configured system. However, with a server with eight sockets the question also arises as to how good performance scaling is from two to four processors. The better the scaling, the lower the overhead usually caused by the shared use of resources within a server. The scaling factor also depends on the application. If the server is used as a virtualization platform for server consolidation, the system scales with a factor of 1.96. When operated with four or eight processors, the system thus achieves twice the performance as with two or four processors, as is illustrated in the diagram opposite using the processor version Xeon Platinum 8180 as an example.

The next diagram illustrates the virtualization performance for increasing numbers of VMs based on the Xeon Platinum 8156 (4-Core) processor.

In addition to the increased number of physical cores, Hyper-Threading, which is supported by all Intel® Xeon® Processor Scalable Family processors, is an additional reason for the high number of VMs that can be operated. As is known, a physical processor core is consequently divided into two logical cores so that the number of cores available for the hypervisor is doubled. This standard feature thus generally increases the virtualization performance of a system.

The scaling curves for the number of tiles as seen in the previous diagram are specifically for systems with Hyper-Threading. 4 physical and thus 8 logical cores are available with the Xeon Platinum 8156 processors; approximately four of them are used per tile (see Benchmark description). So, with a server with eight Xeon Platinum 8156 Processors can use 64 logical cores. This means that a parallel use of the same physical cores by several VMs is avoided up to a maximum of about 16 tiles. That is why the performance curve in this range scales almost ideal. For the quantities above the growth is flatter up to CPU full utilization.
The previous diagram examined the total performance of all application VMs of a host. However, studying the performance from an individual application VM viewpoint is also interesting. This information is in the previous diagram. For example, the total optimum is reached in the above Xeon Platinum 8156 situation with 87 application VMs (29 tiles, not including the idle VMs); the low load case is represented by three application VMs (one tile, not including the idle VM). Remember: the vServCon score for one tile is an average value across the three application scenarios in vServCon. This average performance of one tile drops when changing from the low load case to the total optimum of the vServCon score – from 2.98 to \( \frac{45.6}{29} = 1.57 \), i.e. to 53%. The individual types of application VMs can react very differently in the high load situation. It is thus clear that in a specific situation the performance requirements of an individual application must be balanced against the overall requirements regarding the numbers of VMs on a virtualization host.
STREAM

Benchmark description

STREAM is a synthetic benchmark that has been used for many years to determine memory throughput and which was developed by John McCalpin during his professorship at the University of Delaware. Today STREAM is supported at the University of Virginia, where the source code can be downloaded in either Fortran or C. STREAM continues to play an important role in the HPC environment in particular. It is for example an integral part of the HPC Challenge benchmark suite.

The benchmark is designed in such a way that it can be used both on PCs and on server systems. The unit of measurement of the benchmark is GB/s, i.e. the number of gigabytes that can be read and written per second. STREAM measures the memory throughput for sequential accesses. These can generally be performed more efficiently than accesses that are randomly distributed on the memory, because the processor caches are used for sequential access.

Before execution the source code is adapted to the environment to be measured. Therefore, the size of the data area must be at least 12 times larger than the total of all last-level processor caches so that these have as little influence as possible on the result. The OpenMP program library is used to enable selected parts of the program to be executed in parallel during the runtime of the benchmark, consequently achieving optimal load distribution to the available processor cores.

During implementation the defined data area, consisting of 8-byte elements, is successively copied to four types, and arithmetic calculations are also performed to some extent.

<table>
<thead>
<tr>
<th>Type</th>
<th>Execution</th>
<th>Bytes per step</th>
<th>Floating-point calculation per step</th>
</tr>
</thead>
<tbody>
<tr>
<td>COPY</td>
<td>(a(i) = b(i))</td>
<td>16</td>
<td>0</td>
</tr>
<tr>
<td>SCALE</td>
<td>(a(i) = q \times b(i))</td>
<td>16</td>
<td>1</td>
</tr>
<tr>
<td>SUM</td>
<td>(a(i) = b(i) + c(i))</td>
<td>24</td>
<td>1</td>
</tr>
<tr>
<td>TRIAD</td>
<td>(a(i) = b(i) + q \times c(i))</td>
<td>24</td>
<td>2</td>
</tr>
</tbody>
</table>

The throughput is output in GB/s for each type of calculation. The differences between the various values are usually only minor on modern systems. In general, only the determined TRIAD value is used as a comparison.

The measured results primarily depend on the clock frequency of the memory modules; the processors influence the arithmetic calculations.

This chapter specifies throughputs on a basis of 10 (1 GB/s = 10⁸ Byte/s).

LINPACK

Benchmark description

LINPACK was developed in the 1970s by Jack Dongarra and some other people to show the performance of supercomputers. The benchmark consists of a collection of library functions for the analysis and solution of linear system of equations. A description can be found in the document http://www.netlib.org/utk/people/JackDongarra/PAPERS/hplpaper.pdf.

LINPACK can be used to measure the speed of computers when solving a linear equation system. For this purpose, an $n \times n$ matrix is set up and filled with random numbers between -2 and +2. The calculation is then performed via LU decomposition with partial pivoting.

A memory of $8n^2$ bytes is required for the matrix. In case of an $n \times n$ matrix the number of arithmetic operations required for the solution is $\frac{2}{3}n^3 + 2n^2$. Thus, the choice of $n$ determines the duration of the measurement: a doubling of $n$ results in an approximately eight-fold increase in the duration of the measurement. The size of $n$ also has an influence on the measurement result itself: as $n$ increases, the measured value asymptotically approaches a limit. The size of the matrix is therefore usually adapted to the amount of memory available. Furthermore, the memory bandwidth of the system only plays a minor role for the measurement result, but a role that cannot be fully ignored. The processor performance is the decisive factor for the measurement result. Since the algorithm used permits parallel processing, in particular the number of processors used and their processor cores are - in addition to the clock rate - of outstanding significance.

LINPACK is used to measure how many floating point operations were carried out per second. The result is referred to as $R_{\text{max}}$ and specified in GFlops (Giga Floating Point Operations per Second).

An upper limit, referred to as $R_{\text{peak}}$, for the speed of a computer can be calculated from the maximum number of floating point operations that its processor cores could theoretically carry out in one clock cycle:

$$R_{\text{peak}} = \frac{\text{Maximum number of floating point operations per clock cycle}}{\text{Number of processor cores of the computer} \times \text{Rated processor frequency}[\text{GHz}]}$$

LINPACK is classed as one of the leading benchmarks in the field of high performance computing (HPC). LINPACK is one of the seven benchmarks currently included in the HPC Challenge benchmark suite, which takes other performance aspects in the HPC environment into account.

Manufacturer-independent publication of LINPACK results is possible at http://www.top500.org/. The use of a LINPACK version based on HPL is prerequisite for this (see: http://www.netlib.org/benchmark/hpl/).

Intel offers a highly optimized LINPACK version (shared memory version) for individual systems with Intel processors. Parallel processes communicate here via "shared memory", i.e. jointly used memory. Another version provided by Intel is based on HPL (High Performance Linpack). Intercommunication of the LINPACK processes here takes place via OpenMP and MPI (Message Passing Interface). This enables communication between the parallel processes - also from one computer to another. Both versions can be downloaded from http://software.intel.com/en-us/articles/intel-math-kernel-library-linpack-download/.

Manufacturer-specific LINPACK versions also come into play when graphics cards for General Purpose Computation on Graphics Processing Unit (GPGPU) are used. These are based on HPL and include extensions which are needed for communication with the graphics cards.

\[ R_{\text{max}} = \text{Measurement result} \]
\[ R_{\text{peak}} = \text{Maximum number of floating point operations per clock cycle} \]
\[ \times \text{Number of processor cores of the computer} \]
\[ \times \text{Rated frequency [GHz]} \]

As explained in the section "Technical Data", Intel does not as a matter of principle guarantee that the maximum turbo frequency can be reached in the processor models due to manufacturing tolerances. A further restriction applies for workloads, such as those generated by LINPACK: with intensive use of AVX instructions and a high number of instructions per clock unit. Here the frequency of a core can also be limited if the upper limits of the processor for power consumption and temperature are reached before the upper limit for the current consumption. This can result in the achievement of a lower performance with turbo mode than without turbo mode. In such cases, you should disable the turbo functionality via BIOS option.
